biomvRCNS: Copy Number study and Segmentation for multivariate biological data.

Yang Du*

3 February 2012

Abstract

With high throughput experiments like tiling array and NGS, researchers are looking for continuous homogeneous segments or signal peaks, which would represent chromatin states, methylation ratio, transcripts or genome regions of deletion and amplification. While in a normal experimental set-up, these profiles would be generated for multiple samples or conditions with replicates. In the package biomvRCNS, a Hidden Semi Markov Model and one homogeneous segmentation model are implemented and tailored to handle multiple genomic profiles, with the aim of assisting in transcripts detection using high throughput technology like RNA-seq or tiling array, and copy number analysis using aCGH or targeted sequencing.

1 Introduction

To begin with biomvRCNS, load the package and read the manual page for the main function.

- > library(biomvRCNS)
- > ? biomvRCNS

In the package, 3 main functions are provided for the batch processing of multiple chromosome regions across samples: biomvRhsmm, a hidden semi Markov model (HSMM); biomvRseg, a maximum likelihood based homogeneous segmentation model; and a third biomvRmgmr, custom batch function using max-gap-min-run algorithm. In the following sections we will illustrate their functionalities using example data.

2 Example of array CGH data set of Coriell cell lines

Extracted from packge *DNACopy*, the coriel1 data contains two aCGH studies (GM05296 and GM13330) of Corriel cell lines taken from [Snijders et~al., 2001]. In particular, with 2271 mapped features in total across 22 autosomes and chromosome X.

All three main functions accept common data matrix plus positional information as input or a *GRanges* object with data matrix stored in the meta columns. To get started, we first build a RclassGRanges object from *data.frame*.

```
> data('coriell', package='biomvRCNS')
```

> head(coriell, n=3)

```

Please be sure the data is sorted with respect to their positions before feeding to the models.

2.1 Genomic segmentation with Hidden-semi Markov model

First we use the hidden-semi Markov model with the batch function biomvRhsmm, which will sequentially process each chromosome identified by the seqnames, thus for non-continuous regions on the same chromosome user should give different seqnames to those data. Within this package, there is one argument grp, for the main batch function, which is used to assign data columns to groups according to the experimental design, say technical replicates or biological replicates. Sample columns within the same group could be treated simultaneously in the modeling process as well as iteratively. ¹ In this example, the two profiles are considered independent and not similar, thus been given different values in the grp vector. Additionally there is a built-in automatic grouping method, given a valid clusterm and grp set to NULL.

 $^{^1}$ Simultaneous treatment within group is available for emis.type= 'mvnorm' in biomvRhsmm, poolGrp=TRUE in biomvRmgmr and twoStep=FALSE in biomvRseg.

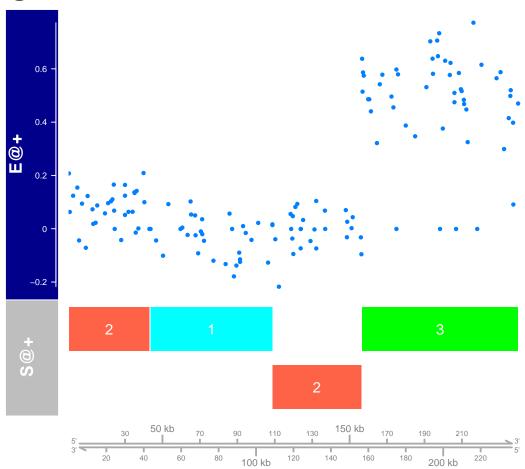

```

In the above run, we limit the model complexity by setting the maxbp to 5E4, which will restrict the maximum sojourn time to maxbp. J is the number of states in the HSMM model, this argument can be given explicitly or estimated from prior information provided in xAnno. Argument soj.type defines the type of sojourn distribution; with Gamma distributed sojourn, the neighbouring position will tend to have the same state, and transit to other states if far apart. Argument emis.type control the distribution of emission probability, in this case the log2 ratio of aCGH data is considered to follow a Normal distribution. The function will then call C codes to estimate the most likely state sequence, with either cMethod='BandF' or cMethod='Viterbi'. The function returns a object of class biomvRCNS, in which the res slot is a GRanges object contain the summary of each estimated segments. There are three meta columns: column SAMPLE gives the column name of which sample this segment belongs to; column STATE, the estimated state for each segments, the lower state number represents state with lower mean value, thus

in this example, a state of 1 could represent region of deletion and 3 for region of duplication, whereas state 2 could be considered copy neutral; column MEAN, gives the segment mean.

A plot method has been implemented for biomvRCNS object using package Gviz, by default the plot method tries to output graphics to multiple EPS/PDF files for each chromosome region and per sample. Here we set tofile=FALSE to output graphics to the current device.

egionID@chr1.0-241000@Coriell.1333

2.2 Using other methods provided in the package

In this section, we use the other two batch functions to process the coriell data. First we use biomyRseg, in which a similar segmentation method like in the package tillingArray is implemented and extended to handle Poison and Negative binomial distributed data. The function shares several argument with biomyRhsmm, like maxbp and grp. The maxseg gives the maximum number of segment per chromosome region, while the optimal number of segment per chromosome region is determined internally by assessing the likelihood with optional penalty terms, by default penalty='BIC' is used. Another option is to use modified Bayes information criterion penalty='mBIC' as in the CBS algorithm used in DNAcopy. The function proceed in the following manner: assuming within each group sample columns exhibit similar patterns, and thus be processed simultaneously in the first step. By maximizing the likelihood the optimal number of segments is selected for each group. And in a second step if twoStep=TRUE the candidate segments produced in the first step are merged with respect to each sample, thus forcing sample columns in the same group to have a more unified segmentation result yet keeping it possible to have sample specific pattern.

```
> resseg<-biomvRseg(x=xgr, maxbp=1E4, maxseg=10, family='norm', grp=c(1,2))
```

> head(resseg@res)

After the example run, the function returns a biomvRCNS object, containing similar information as the previous biomvRhsmm run, except that the STATE column now only have a binary state value of either "HIGH" or "LOW", which is simply graded as 'HIGH' if the segment mean is higher than the grand mean of the whole region, and 'LOW' otherwise.

NA

NA

NA

NA

It is also possible to use the simple max-gap-min-run algorithm to segment aCGH profiles, by calling biomvRmgmr. But due to the binary nature of the algorithm, one have to run twice in order to get both extremely high and low regions, then combine the resulting *GRanges* manually.

```
> resmgmrh<-biomvRmgmr(x=xgr, q=0.9, high=TRUE, maxgap=1000, minrun=2500, grp=c(1,2))
> resmgmrl<-biomvRmgmr(x=xgr, q=0.1, high=FALSE, maxgap=1000, minrun=2500, grp=c(1,2))
> res<-c(resmgmrh@res, resmgmrl@res)</pre>
```

3 Example of RNA-seq data from ENCODE

The data contains gene expressions and transcript annotations in the region of the human TP53 gene (chr17:7,560,001-7,610,000 from the Human February 2009 (GRCh37/hg19) genome assembly), which is part of the long RNA-seq data generated by ENCODE/Cold Spring Harbor Lab, containing 2 cell types (GM12878 and K562) with 2 replicates each.

To generate local read counts, alignment files were pulled from UCSC (http://hgdownload.cse.ucsc.edu/goldenPath/hg19/encodeDCC/wgEncodeCshlLongRnaSeq/) using package Rsamtools. And subsequently reads were counted in each non-overlapping unit sized window for the region (chr17:7,560,001-7,610,000). In the pre-compiled data encodeTP53, a window size of 25bp was used with the chunk of code below.

The pre-compiled data encodeTP53 also includes the regional annotation of TP53 RNAs isoforms, gmgr, which were derived from the ENCODE Gene Annotations (GENCODE), subset to only isoforms of TP53 gene. http://hgdownload.cse.ucsc.edu/goldenPath/hg19/encodeDCC/wgEncodeGencodeV4/wgEncodeGencodeManualV4.gtf.gz).

```
> af <- system.file("extdata", "gmodTP53.csv", package = "biomvRCNS")
> gtfsub<-read.table(af, fill=T, stringsAsFactors=F)
> idx<-gtfsub[,3]=='CDS' | gtfsub[,3]=='UTR'
> gmgr<-GRanges("chr17", IRanges(start=gtfsub[idx, 4], end=gtfsub[idx, 5],
+ names=gtfsub[idx, 13]), strand='-', TYPE=gtfsub[idx, 3])</pre>
```

3.1 Transcript detection with Hidden-semi Markov model

We first load the encodeTP53 data, poll the read counts for each cell type and add 1 to the base count to increase stability.

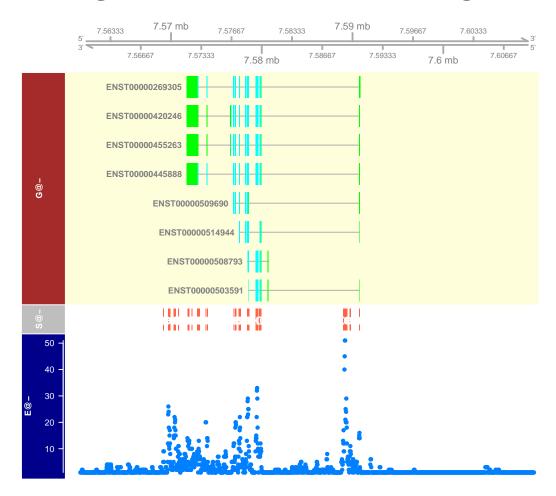

For count data from sequencing, the emis.type could be set to either 'pois' or 'nbinom', though 'pois' is preferred for sharp boundary detection. For the sojourn settings, instead of using the uninformative flat prior, we here use estimates from other data source as a prior. We load the TxDb.Hsapiens.UCSC.hg19.knownGene known gene database, and pass the TranscriptDb object to xAnno. Then internally sojourn parameters and state number J will be estimated from xAnno by calling function sojournAnno. The three states estimated would each represents 'intergenic', 'intron', 'exon'.

As in the ENCODE guide [Consortium, 2011], the study identified the p53 isoform observed in K562 cells has a longer 3'UTR region than the isoform seen in the GM12878 cell line. So here we plot our model estimates and consider the third state, namely 'exon', to represent detected transcripts. And the HSMM model clearly picked up the extra transcripts of the K562 cell line at the 3'UTR.

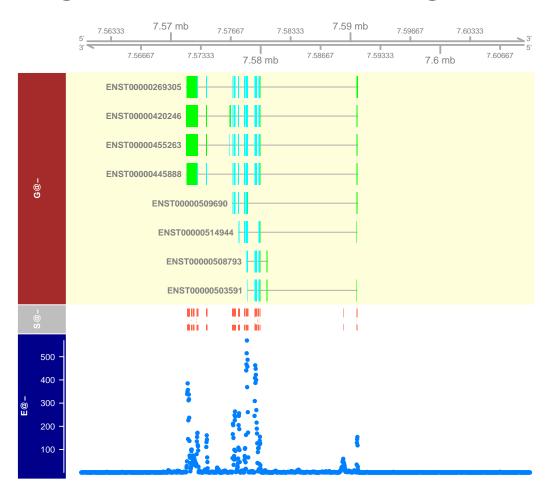

```
> reshsmm@res[mcols(reshsmm@res)[,'STATE']=='exon']
```

```
